AAAI'18 Technical Track — February 2-7 2018, New Orleans

Context

Imagine a user wants to book a dinner online. A menu is a tuple of values of three different attributes:

Main course (M) meat or fish

Wine (W) red or white

Cheese (C) goat or Camembert

During her choice, we would like to make a recommendation
We have access to a set of previously menus sold by the website

Example

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – white – goat</i>
<i>fish – white – Cam.</i>

Example

- Meat more common than fish: meat is probably preferred to fish

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – white – goat</i>
<i>fish – white – Cam.</i>

meat > *fish*

Example

Sales history

meat – red – goat
meat – red – goat
meat – red – Cam.
meat – red – Cam.
meat – red – Cam.
meat – white – goat
meat – white – Cam.
fish – white – goat
fish – white – Cam.

- Meat more common than fish: meat is probably preferred to fish

meat > fish

- For meat dinner, red wine seems preferred to white wine

meat : red > white

Example

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – white – goat</i>
<i>fish – white – Cam.</i>

- Meat more common than fish: meat is probably preferred to fish

meat > fish

- For meat dinner, red wine seems preferred to white wine

meat : red > white

We can deduce information about user preferences
!

Probabilistic model

We don't always choose our most preferred outcome
(e.g. because of a desire of variety)

Ground idea

- The more preferred an outcome is, the more often it is chosen
- **Probability distribution of selection p decreasing w.r.t. the preference relation \succ : $p(o) > p(o')$ iff $o \succ o'$**

Idea not tied to any specific language

In the following: represented by lexicographic preference trees

- 1 Introduction
 - Context and problematic
 - Probabilistic model
- 2 **Lexicographic Preference Trees**

 - Application to recommendation in car interactive configuration

Lexicographic Preference Trees (LP-trees) [BCL⁺09]

LP-tree definition [BCL⁺09]

- Tree of attributes ordered by importance (root: most important)
- Edges can be labelled by a value or not
- Preferences rules associated to each node

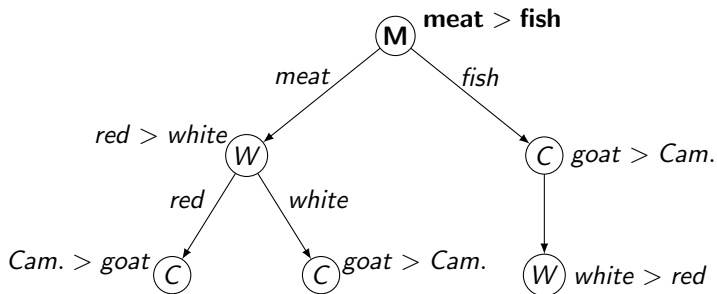

LP-trees semantics

We would like to compare:

meat – red – goat and *fish – white – goat*

LP-trees semantics

We would like to compare:

$meat - red - goat \succ fish - white - goat$

Any menu with meat is preferred to any menu with fish

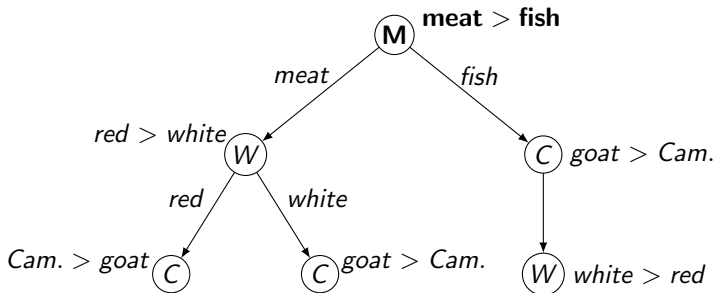

LP-trees semantics

We would like to compare:

meat – white – goat and *meat – white – Cam.*

LP-trees semantics

We would like to compare:

meat – white – goat and *meat – white – Cam.*

Root node can't decide the comparison

LP-trees semantics

We would like to compare:

meat – white – goat and *meat – white – Cam.*

Among meat menus, any menu with red wine is preferred to any menu with white wine

LP-trees semantics

We would like to compare:

meat – white – goat \succ *meat – white – Cam.*

Our contribution

Learning algorithms assume pairwise comparisons
[BCL⁺09, BCL⁺10, BH12, LT15, BHKG17]

Here, no pairwise comparisons but sales histories

Our contribution

An algorithm to learn a LP-tree from sales histories

How to learn a LP-tree from a sales history ?

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – red – goat</i>
<i>fish – white – goat</i>

How to learn a LP-tree from a sales history ?

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – red – goat</i>
<i>fish – white – goat</i>

<i>M</i>	7 meat	2 fish
<i>W</i>	6 red	3 white
<i>C</i>	5 goat	4 Cam.

1. **Most important attribute**
= most unbalanced attribute

How to learn a LP-tree from a sales history ?

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – red – goat</i>
<i>fish – white – goat</i>

<i>M</i>	7 meat	2 fish
<i>W</i>	6 red	3 white
<i>C</i>	5 goat	4 Cam.

1. **Most important attribute**
= most unbalanced attribute

How to learn a LP-tree from a sales history ?

Sales history		
<i>meat – red – goat</i>		
<i>meat – red – goat</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – white – goat</i>		
<i>meat – white – Cam.</i>		
<i>fish – red – goat</i>		
<i>fish – white – goat</i>		

<i>M</i>	7 meat	2 fish
<i>W</i>	6 red	3 white
<i>C</i>	5 goat	4 Cam.

2. Preference relation

How to learn a LP-tree from a sales history ?

3. Most important attribute for *meat* menus

Sales history
<i>meat</i> – <i>red</i> – <i>goat</i>
<i>meat</i> – <i>red</i> – <i>goat</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>white</i> – <i>goat</i>
<i>meat</i> – <i>white</i> – <i>Cam.</i>
<i>fish</i> – <i>red</i> – <i>goat</i>
<i>fish</i> – <i>white</i> – <i>goat</i>

How to learn a LP-tree from a sales history ?

Sales history		
<i>meat – red – goat</i>		
<i>meat – red – goat</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – white – goat</i>		
<i>meat – white – Cam.</i>		
<i>fish – red – goat</i>		
<i>fish – white – goat</i>		
W	5 red	2 white
C	3 goat	4 Cam.

3. Most important attribute for *meat* menus

How to learn a LP-tree from a sales history ?

Sales history		
<i>meat – red – goat</i>		
<i>meat – red – goat</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – red – Cam.</i>		
<i>meat – white – goat</i>		
<i>meat – white – Cam.</i>		
<i>fish – red – goat</i>		
<i>fish – white – goat</i>		
W	1 red	1 white
C	2 goat	0 Cam.

4. Most important attribute for *fish* menus

How to learn a LP-tree from a sales history ?

5. No exemple in the branch *fish* – *Cam.* !

Sales history
<i>meat</i> – <i>red</i> – <i>goat</i>
<i>meat</i> – <i>red</i> – <i>goat</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>red</i> – <i>Cam.</i>
<i>meat</i> – <i>white</i> – <i>goat</i>
<i>meat</i> – <i>white</i> – <i>Cam.</i>
<i>fish</i> – <i>red</i> – <i>goat</i>
<i>fish</i> – <i>white</i> – <i>goat</i>

How to learn a LP-tree from a sales history ?

6. Solution: one unlabelled, unconditioned edge

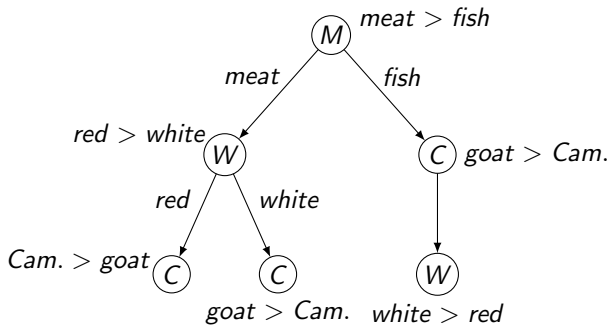

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – red – goat</i>
<i>fish – white – goat</i>

How to learn a LP-tree from a sales history ?

7. And so on

Sales history
<i>meat – red – goat</i>
<i>meat – red – goat</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – red – Cam.</i>
<i>meat – white – goat</i>
<i>meat – white – Cam.</i>
<i>fish – red – goat</i>
<i>fish – white – goat</i>

Algorithm

Algorithm 1: LP-tree learning algorithm

Input: \mathcal{X} , a set of outcomes \mathcal{H} over \mathcal{X}

Output: \mathcal{L} the learnt k -LP-tree

Algorithm LearnLPtree(\mathcal{X}, \mathcal{H})

```
1   $\mathcal{L} \leftarrow$  unlabelled root node
2  while  $\mathcal{L}$  contains some unlabelled node  $N$  do
3     $(\mathbf{X}, \text{table}) \leftarrow$  ChooseAttributes( $N$ )
4    label  $N$  with attributes  $\mathbf{X}$  and CPT  $\text{table}$ 
5     $L \leftarrow$  GenerateLabels( $N, \mathbf{X}$ )
6    for each  $l \in L$  do add new unlabelled node to  $\mathcal{L}$ , attached
    to  $N$  with edge labelled with  $l$ 
7  return  $\mathcal{L}$ 
```

Properties

Time complexity

For n attributes and a sales history \mathcal{H} , the time complexity is:

$$O(n^2 |\mathcal{H}|^2)$$

Property 1

This algorithm converges to the target LP-tree as the sample size tends to infinity

Property 2

This algorithm finds the most probable linear LP-tree

- 1 Introduction
 - Context and problematic
 - Probabilistic model
- 2 Lexicographic Preference Trees
 - Lexicographic Preference Trees
 - Learning algorithm
 - Algorithm properties
- 3 Experiments
 - Experiments on generated data
 - Application to recommendation in car interactive configuration

Experiments on generated data: protocol

Experimental protocol

- LP-trees are randomly generated
- Sales histories are drawn from a geometric distribution p
- LP-trees are learnt from the sales histories
- Learnt LP-trees are compared with hidden LP-trees

Original LP-tree

Experiments on generated data: protocol

Experimental protocol

- LP-trees are randomly generated
- Sales histories are drawn from a geometric distribution p
- LP-trees are learnt from the sales histories
- Learnt LP-trees are compared with hidden LP-trees

Experiments on generated data: protocol

Experimental protocol

- LP-trees are randomly generated
- Sales histories are drawn from a geometric distribution p
- LP-trees are learnt from the sales histories
- Learnt LP-trees are compared with hidden LP-trees

Experiments on generated data: protocol

Experimental protocol

- LP-trees are randomly generated
- Sales histories are drawn from a geometric distribution p
- LP-trees are learnt from the sales histories
- Learnt LP-trees are compared with hidden LP-trees

Experimental evaluation

Items in the sales history are probably ranked high in user preferences
A good LP-tree should rank high the items of the sales history

Evaluation of the LP-tree learnt

- Induction principle: minimize mean rank of items in the sales history
- **Ranking loss** = normalized difference of mean rank of items in the learnt LP-tree and the target LP-tree

Experiments on generated data: results

Legend

- Unpruned LP-tree
- + Pruned LP-tree
- x Linear LP-tree

Results

- Quick convergence w.r.t. sample size: ranking loss seems inversely proportional to the sample size

Recommendation in car interactive configuration: dataset

Dataset

- Genuine sales history from Renault (car manufacturer)
- 48 attributes (mostly binary)
- 27088 items in sales history

From this sales history, we learn a LP-tree

Recommendation in car interactive configuration: protocol

Interactive configuration

- 1 The user selects freely an attribute
- 2 The recommender system recommends a value
- 3 The user accepts the recommended value or chooses another one
- 4 Repeat until all attributes have a value

Protocol

- For each car in the test set, we simulate a configuration session
- Recommendation precision: ratio of recommendations that would have been accepted

Recommendation in car interactive configuration: results

Legend

- k = 1
- ▲ k = 2
- × k = 3

Results

- Mean rank correlated with measured precision
- High precision (87% accepted recommendations)

Conclusion

Contributions

- Ground idea: preferred outcomes are more probably picked
- Framework and algorithm to learn LP-trees from **positives examples**
- Effective learning of randomly generated LP-trees
- Good recommendation precision on a real-world application

Perspectives

- Sample complexity in PAC settings
- Extension to other preference languages (e.g. CP-nets)

Linear LP-trees

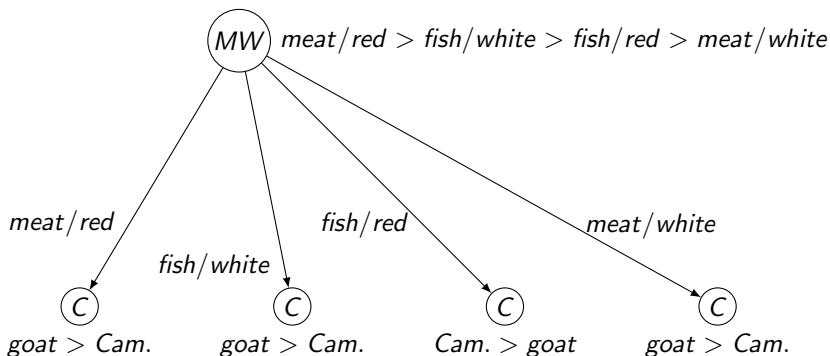

A linear LP-tree is a LP-tree with only unlabelled edges (i.e. a linear tree)
It is the classical “lexicographic order”.

k -LP-trees

k -LP-trees may have at most k attributes per node (classical LP-trees are 1-LP-trees)

It can represent preference order where classical LP-trees can't

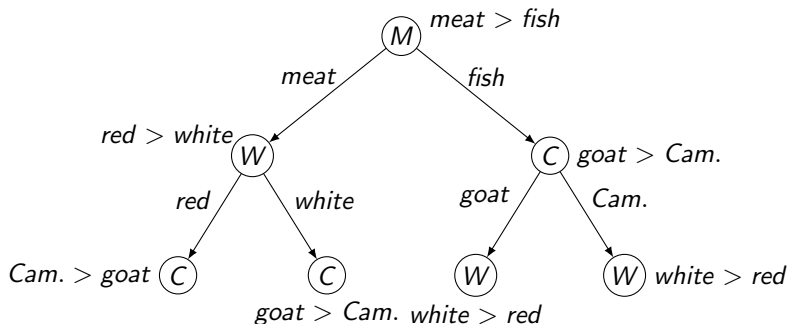

LP-tree pruning

The LP-tree learnt may overfit (learn by heart) the data, which decrease its generalization power

The pruning reduces overfitting by simplifying the LP-tree

Before pruning

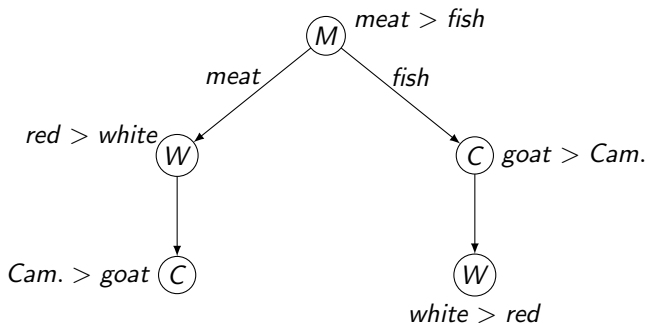

LP-tree pruning

The LP-tree learnt may overfit (learn by heart) the data, which decrease its generalization power

The pruning reduces overfitting by simplifying the LP-tree

After pruning

Clustering

We divide the sales history into homogeneous clusters
We learn a LP-tree for each cluster

Then, to make a recommendation given a partial assignment \mathbf{u} , we use the LP-tree whose cluster centre is closest (Hamming distance) to \mathbf{u}
